

Autism Spectrum Disorder (ASD) is a neurodevelopmental disability characterized by focused interests, repetitive interaction (APA, 2013). Many autistic individuals show differences in the production and perception of natural speech (Paul et al., 2005a), particularly with respect to speech prosody [i.e., changes in speech duration, loudness, and intonation (Keween & Zhang, 2023)], which plays an important role in social communication for autistic individuals (Mann & Karsten,

and rhythm of speech (Asperger, 1944; Kanner, 1943), characteristics which are still considered diagnostically today [see Autism Diagnostic Interview-Revised (ADI-R; Lord et al., 1994)]. In the subsequent sections of this introduction, we will discuss various aspects of prosody in autism. Specifically, we will examine the features exhibited by autistic individuals and how these differences impact the perception of social competence. We will also examine the role of parents as early models of speech and communication for both autistic and non-autistic children and discuss how adults adapt their speech patterns based on the needs of the child.

Parents also completed the self-report version.

Social Competence

Caregivers completed the MSCS (Yager & Iarocci, 2013),
y jkej "tgs wktgu" rctgpvu" vq" tcvg" vj gkt" ej knfou" dg j cxkqwt" qp"
7 domains of social competence: social motivation, social
inferencing, emotion regulation, nonverbal sending skills,
demonstrating empathic concern, social knowledge, and
verbal conversation skills. Parents also completed a self-
report version of the MSCS. The overall score created by
combining all subscales is used in the current study. The
MSCS has been shown to have good internal consistency
* $\alpha > 0.84$), as well as strong convergent validity with other
tests of social competency (social responsiveness scale, $r =$
 -0.89 , $p < .001$; Yager & Iarocci, 2013).

Data Analysis

Recordings of mother-child interactions ranged from 615 to 3,648 s, with an average length of 1,473 s. Audio was extracted from the video recordings of each mother-child

scores could be accounted for ($R^2 = 0.779$, $F(6, 11) = 6.495$, $p = .004$; see Table 2).

Future work should aim to elucidate whether pitch modulations in autistic children's speech are meaningful and serve communicative purposes. Alternatively, it is possible that the lack of a meaningful relationship between prosodic characteristics and social competence in autistic children is commonly reported (Hubbard et al., 2017; Nadig & Shaw, 2012; Paul et al., 2005a, b; Shribeg et al., 2001), autistic children's speech lacks social cues (Ashwin et al., 2015; Greene et al., 2011; Jellema et al., 2009; Lott-Sandkamp et al., 2023), perspective-taking (Bamicha & Drigas, 2022
